

DSCForge

Stop hand-authoring DSC v3 YAML one property at a time.

DSCForge is a web-based DSC v3 authoring studio that turns natural language, GPO exports, and live system scans into schema-validated configurations, proves them on real Hyper-V, Proxmox, UNRAID, and physical targets, then publishes them to ConfigFabric and Intune, all from one local HTTPS server.

Describe it. Validate it. Prove it on real hardware.

Multi-model Proven

local or cloud LLMs, compared side-by-side with a QA gate

applied on real targets, reverted to a clean state*

*Push a draft to a disposable Hyper-V, Proxmox, UNRAID, or physical target, apply it with the DSC v3 CLI, read the real result, then revert to a clean snapshot. You validate on hardware, not on hope. Physical targets revert via the Unified Write Filter on reboot.

AI authoring, schema-aware

Turn natural language into DSC v3 YAML across a pool of local or cloud models. A live validation badge, structure-aware repair, and N-endpoint compare with a QA approve / reject gate keep the output correct, not just plausible.

Proven on real hardware

Apply a draft on Hyper-V, Proxmox, UNRAID, or a physical device with the Unified Write Filter, read the real result, then revert to a clean snapshot. Gap analysis and per-endpoint token tracking round it out.

Brownfield-ready

Collect RSoP or a GPO backup and convert Group Policy to DSC v3. Search a full ADMX catalog graded for v3 convertibility, and blend legacy v1 / v2 resources through the WindowsPowerShell adapter.

Hands off to the fabric

An Azure Portal-style web UI on a local HTTPS server with auto-generated certificates. Publish validated configs straight to ConfigFabric for group-based assignment, or export for Intune.

How it compares Differentiators first. ★ marks capabilities the alternatives cannot do out of the box.

Capability	Hand-authored DSC v3	Generic AI assistant	DSCForge
★ Schema-aware generation & repair	Type YAML by hand against the schema docs, then run <code>dsc.exe</code> and read the errors.	Emits plausible YAML with no live schema, so wrong property names and mixed conventions slip through.	Generates against the resource schema, shows a live validation badge, and runs structure-aware repair so native and legacy conventions never mix.
★ N-endpoint compare with QA	One person, one draft. No second opinion.	One model, one answer. No side-by-side, no approval gate.	Run 2+ endpoints side-by-side with a multi-column diff, then approve or reject the winner in a QA workflow.
★ Prove on real targets	Stand up and tear down your own test VMs by hand.	No notion of a target. You test it yourself, somewhere else.	Apply on Hyper-V, Proxmox, UNRAID, or physical (UWF) targets, read the real result, then revert to a clean snapshot.
★ GPO to DSC v3 conversion	Read each policy and translate it to DSC by hand.	Paste settings into a chat and hope the translation is faithful.	Collect RSoP or a GPO backup and convert Administrative Templates, security, audit, firewall, and more to DSC v3.
ADMX policy catalog	Grep <code>PolicyDefinitions</code> on disk yourself.	No catalog. Relies on the model's memory.	Searchable ADMX catalog with ADML display names and per-setting DSC v3 convertibility grading.
Legacy DSC v1 / v2 resources	Author <code>WindowsPowerShell</code> adapter blocks by hand and keep conventions straight.	Often mixes v3 and legacy property styles in one document.	Blends legacy v1 / v2 via the adapter, including third-party modules introspected from private NuGet repos.
AI provider choice	Not applicable.	One hosted model, no failover, no usage visibility.	Pool Ollama, GitHub Copilot, llama.cpp, Claude, or any OpenAI-compatible endpoint with priority, failover, and per-endpoint token tracking.
Authoring surface & handoff	Text editor and CLI. Copy the result wherever it needs to go.	Chat window. Copy-paste into your editor.	Azure Portal-style web UI on a local HTTPS server, then publish validated configs to ConfigFabric or export for Intune.
